

EcoSolvelt project case study

- **What problem did it solve ?**

The biggest problem we solve is the gap between citizens and local authorities when it comes to addressing environmental issues in their cities. City boards often fall short of maintaining certain areas, leaving problems like garbage pileups, potholes, and broken street lights unresolved for extended periods. 'EcoSolvelt' provides a platform that empowers citizens to take matters into their own hands by contributing to the resolution of these issues through manual labor, financial donations, or item donations, all while fostering a sense of community around shared local concerns.

- **Who was it for ?**

Our two main stakeholders are

- **Admins** : Website administrators can create and publish events centered around specific environmental problems, and oversee the overall activity and integrity of the platform. They can also manage registered users and donations.
- **Citizens** : Registered users can create their own events to flag and address environmental problems in their city with specific details about the issue, sign up and participate in existing events, and contribute through manual labor, financial donations, or item donations. They can also submit complaints about the website itself or about issues that arose during any events.

- **What I personally built ?**

I was personally responsible for developing the events feature, which allows both admins and citizens to create events with specific details about the environmental problem they want to address (e.g., street pollution, beach cleanup, broken street lights). I also developed the event participation feature, enabling users to sign up and take part in events. Additionally, I built the complaints feature, which provides a contact form for users to report concerns either about the website itself or about issues related to specific events. Beyond development, I was responsible for delegating and coordinating tasks between team members, creating and

managing the GitHub repository, handling pull requests, merge conflicts, and branches, as well as supervising the database.

- **What technologies were used ?**

We were limited by our university professor to use plain PHP for this project and we used a simple MySQL database.

- **What's the current status ?**

The academic project is finished and delivered to our university professor but it hasn't been deployed to any platform since we were only asked to provide an application that runs locally on the machine.
